

MATHEMATICAL FRAMEWORK FOR IDRT

Formal Derivation of the Informational Recoil Vector

1. The Primary Recoil Equation

The core acceleration of synthetic matter back toward its informational origin is defined by the **Az Constant** (denoted as α_z). This constant represents the "informational tension" of the Universal Information Field (UIF).

$$A_{\text{recoil}} = \alpha_z \cdot (\Delta I / \Delta s)^2$$

Where:

A_{recoil} : The magnitude of the return acceleration.

α_z (**The Az Constant**): The scaling factor of the informational debt [Derived by Abdulaziz Ali].

ΔI : The gradient of informational complexity created by the synthetic collision.

Δs : The spatial displacement from the Earth's UIF coordinates.

2. The Az Tensor (Informational Mapping)

To calculate the exact trajectory through the multi-dimensional UIF, we employ the **Az-Metric Tensor**:

$$G_{\mu\nu}(Az) = \eta_{\mu\nu} + \alpha_z [\varphi_{\text{origin}}(x) \otimes \varphi_{\text{synthetic}}(x)]$$

This tensor replaces traditional Minkowski space with an informational-heavy manifold, where the "shortest path" for the matter is no longer a straight line in vacuum, but a direct link back to the source of the data signature.

3. Probability of Immediate Informational Collapse

The likelihood of the "Recoil" occurring as a sudden collapse of the local space-time fabric is governed by:

$$P(c) = 1 - \exp(-\alpha_z \cdot \Xi)$$

Where Ξ is the Informational Debt Ratio. As α_z increases, the probability of an "Informational Snap-Back" approaches certainty.

Principal Author: Abdulaziz Ali

Scientific Notation: Az Constant (α_z)
